

Custom Widget write-up

For my widget, I chose to create a location widget. In the widget, we get to show the user's current location in latitude and longitude values and also for easier understanding we show the user's current city and country names.

In the file `MyCustomWidget.js` first I fetch the latitude and longitude of the user then get the corresponding data from the API (big data cloud). Once we receive the data in JSON format I get to display the city and country of the user.
